

Urinary stone removal by urologic endoscopy

A urinary stone in the ureter or kidney is removed by endoscopy through the urethra. The procedure requires general or local anesthesia.

After the procedure

- You may move around and eat normally.
- Discharge is on the next day. If the procedure is made as day-surgery, you discharge is on the same day.
- The duration of sick leave after the procedure is determined on the basis of your individual situation but is usually a few days.
- Your urine may be blood-stained for a few days after the procedure. You should drink plenty of liquid (1.5–2 liters per day) – this promotes clearing of the urine from blood and recovery of the urinary tract after the procedure.

Follow-up

- Follow-up and the need for check-ups after the procedure are decided individually as determined by the urologist.
